

# Customer Journey Map

|      |                   |         |                 |              |                                                |               |         |
|------|-------------------|---------|-----------------|--------------|------------------------------------------------|---------------|---------|
| Date | 29 September 2026 | Team ID | SWTID-2026-8065 | Project Name | Implement Client Script & UI Policy (Incident) | Maximum Marks | 2 Marks |
|------|-------------------|---------|-----------------|--------------|------------------------------------------------|---------------|---------|

Map the Incident user's experience stage-by-stage based on the documented UI Policy and Client Script workflow.

| Phase of Journey                                                     | Stage 1                                                                                                  | Stage 2                                                                                              | Stage 3                                                                                                        |
|----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| Actions<br><i>What does the customer do?</i>                         | Open/create an Incident and enter the required Incident information. Set Impact to High when applicable. | Change Impact to High, observe Urgency being set automatically, and try to save without Assigned To. | Change Impact back to Medium, verify fields become editable as appropriate, and attempt list editing of State. |
| Touchpoint<br><i>What part of the service do they interact with?</i> | Incident form; Impact field; Assignment group; Assigned To                                               | Impact field; Urgency field; Assigned To field; UI Policy; onChange and onSubmit Client Scripts      | Incident form; Incident list; State field; onCellEdit Client Script                                            |
| Customer Thought<br><i>What is the customer thinking?</i>            | The form should guide me and make it clear what information is required.                                 | I expect the system to apply the rules automatically and tell me what is missing.                    | I want valid changes to work from the form, while restricted list edits should be blocked.                     |
| Customer Feeling<br><i>What is the customer feeling?</i>             | Needs clear field behavior and consistent data entry.                                                    | The user gets immediate feedback and cannot submit incomplete High Impact data.                      | Clear restrictions with expected behavior make Incident updates consistent.                                    |
| Process Ownership<br><i>Who is in the lead on this?</i>              | ServiceNow user / Incident form configuration                                                            | UI Policy and Client Scripts                                                                         | Incident management configuration / Client Scripts                                                             |
| Opportunities<br><i>How can we improve this stage?</i>               | Use UI Policy conditions to control mandatory behavior and field interaction when Impact is High.        | Keep automatic updates and validation messages clear so users understand why a save is blocked.      | Test reverse conditions, successful form updates, and list-edit blocking to maintain data integrity.           |

**Source basis:** Project documentation states that UI Policies and Client Scripts are used to control field behavior, auto-populate Urgency, prevent saving when Assigned To is missing for High Impact incidents, block direct State list edits, and test reverse/successful update behavior.
